

M18.3 Solution Guide - Baselineing

In this activity, you determined thresholds by baselining activity from a Windows server's activity.

-
1. Upload the provided Windows log file:
 - Select **Settings > Add Data**, and add the `windowsrawlogs.txt`.
 2. Design a search to look at failed logins:
 - `source="windowsrawlogs.txt" EventCode=4625`
 3. Determine when the attack happened:
 - A spike occurred at approximately 7 a.m. on February 11, 2020. This is indicated by a much higher count of activity compared to the other hours.
 4. Determine the approximate average of normal bad logins per hour:
 - Based on the `bad_logins` per hour, the number is approximately two per hour.
 5. Determine a threshold of logins that will alert if a brute force is occurring.
 - There is no perfect answer to this: thresholds may be adjusted as the normal count of bad logins and the count of attacks changes.
However, based on the normal average of bad logins vs. attacks, setting a threshold to seven bad logins per hour would likely identify attacks and minimize false positives.
