

## Module 21 Day 1: Escalate or Not?

### Activity Introduction

- In this activity, you are SOC analysts working for a financial services organization that has experienced multiple security issues.
- Your task is to review the following issues and determine if these require escalation to the SIRT

### Instructions

Review the following seven security incidents, and determine if you would escalate them to the SIRT. Additionally, if you determine they require escalation, note what additional staff may be required to assist with responding to this incident.

1. An employee notified the SOC that they received a potential phishing email. They let you know they have not clicked on any links or responded to the email in any manner.
2. An alert went off in your endpoint detection system. The alert indicated that an engineer potentially downloaded malware that may be ransomware.
3. Your application monitoring solution indicates that one source IP address is attempting to brute force an administrator account. All indicators show that the attempt is unsuccessful.
4. Your network monitoring solution has detected a DDoS attack, the attack volume has been significant enough to impact the performance of your network.
5. An employee notified the SOC that they determined a customer database with PII was potentially accessible from the internet. While no indications a malicious attacker has accessed this database, the database was accessible for over 30 days.
6. Several customers of your banking application determined there was a cross-data issue, where they logged in and were able to view accounts and names of other banking customers. The customers did not have malicious intent, they just notified the organization of this issue.
7. Your endpoint monitoring solution detected an employee trying to connect a USB device to their computer, which is against the organization's policies.
