

Activity File: Installing Packages

Now that we have stopped a malicious service from running and completed a basic audit, we're going to cover some of the miscellaneous utilities that we can install onto our VMs. Specifically, we'll install the following services:

- emacs is a traditional file editor.
- cowsay is a utility that takes in input and displays a cow repeating it.

Instructions

1. Many of these files will install in the `/usr/games` directory, which is not part of the `$PATH` variable
 - Run `echo "export PATH='/usr/games:$PATH' " >> .bashrc && source .bashrc` to update the `$PATH` variable.
2. To install the packages `emacs` and `cowsay`, you will need to use the command that you have learned from the Installing Packages lecture.
Each time you install a package, `apt` will ask for permission to use the disk space needed to install the package.
 - Use the man pages to find a flag that lets you automatically answer yes to any prompts that come up when installing a package.
 - Install the remaining packages by using this command.
3. Next we will want to use our new packages. Use the following commands to run your new utilities:
 - `emacs` will open your new text editor.
 - `cowsay hello` will start a new line with a cow saying "hello."

Bonus

4. Find the command that will let you install multiple packages with a single command.
5. Run the following command:
 - `cowsay "Linux is Fun!"`
