

Module 6 - Day 1: Custom Commands

- In the previous activity, you created your first Bash script. It contained a series of commands that should save you time during your system audits.
- In this activity, you will continue to make this script more complex by adding a few commands from the first exercise.
- As a bonus, you will save this script to a `scripts` directory and add that directory to your `$PATH` so that you can call your script directly on the command line, from any directory.

Completing this activity will require the following:

- Ensure your script from the last activity runs as expected.
- Add the new commands listed in the instructions to your script.
- Save your script in a `~/scripts` directory.
- Add your `~/scripts` directory to your `$PATH`.
- Run your script to verify it produces the correct output.

Instructions

Complete the following inside your script.

- Add the command for creating a `~/research` directory to your script.
- Add the command for finding executable files to your script.
- Add the command for finding the top 10 processes to your script.
- Modify each command of the script so that it writes all output to a file called `~/research/sys_info.txt`.

Bonus

Complete the following in your command line environment:

- Manually create a `~/scripts` directory and save your script there. (This should not be part of your script.)
- Add your `~/scripts` directory to your `$PATH`.
- Reload your `bashrc` file.
- Run your script.
- Open `~/research/sys_info.txt` and verify that it has the desired output.
