

Module 6 - Day 1: Sysadmin Bash Script

- In the previous activity, you created several aliases and saved them to your `~/.bashrc` file. You may have noticed that creating long strings of commands can get a bit cumbersome when working on the command line.
- Now, we will put our commands into a script file. Reading, writing, and running Bash scripts are a staple of any good sysadmin.
- In this activity, you will create a script that completes several system audit steps automatically.

When completing this activity, consider the following:

- Start by ensuring each command will give you the expected output before adding it to your script.
- Some commands may not have been covered and require additional research.
- Add all the commands listed in the instructions to your script.
- Ensure the output of each command has a title like: `The Memory Info is:`
- Change the permissions on your script to make it executable.
- Run your script to verify it produces the correct output.

As a reminder, here are a few helpful environment and shell variables:

- `USER`
- `HOME`
- `SHELL`
- `PWD`
- `Bash`
- `HOSTNAME`
- `MACHTYPE`
- `UID`

Instructions

Complete the following setup:

- Create a new script file called `sys_info.sh`.
- Change the permissions on the file to make it executable.
- Open the file with `nano`.

Activity File

- Add a top `hashbang` (declarative statement) line to make this a Bash script.

Your script should output the following data:

- A title and today's date
- The `uname` info for the machine
- The machine's `eth0` IP address (Narrow this output down to one line.)
- The hostname

Run your script using `./` notation.

Bonus Script Ideas

If you complete the script above, try adding a few of these items:

- The DNS info
 - The Memory info
 - The CPU info
 - The Disk usage
 - The currently logged-on users
-
