

Common Windows Module Issues and How to Resolve Them

Issue: Windows 10 Failed to Restore | Deleting the Saved State

The Hyper-V VMs may not shut down properly if they are idle for an extended period of time—instead, the Hyper-V machine can go into a hibernation state known as a “saved state.”

If a machine goes into a saved state, you may see the error shown in the following image: **The application encountered an error while attempting to change the state of the <virtual machine>.**

When This Occurs

This can happen at any time. It's likely to occur the first time you attempt to launch the Windows 10 Hyper-V VM, but it can also occur any time you restart your lab.

Solution

You will need to **open PowerShell** within the Windows RDP Host machine and run the following command:

```
Get-VMSnapshot | Remove-VM SavedState
```

This will remove the saved states. After deleting the saved state, you can turn on the Windows 10 and Windows Server virtual machines by running:

```
Get-VM | Start-VM
```

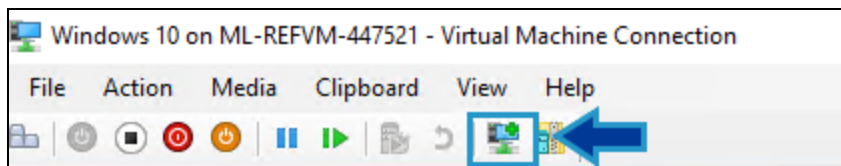

If you are unsure how to launch PowerShell, click on the bottom-left Start menu button and type “PowerShell”.

Note: If you encounter this error, the VM will not start up until you delete the saved state. To avoid this in the future, turn the VMs and the host machine off when not in use.

Issue: Virtual Machine Screen Is Cut Off

If you only see a partial window after launching a virtual machine, remedy it by toggling **Enhanced Session Mode** on and off. To do so:

- Press the enhanced-session-mode icon in the top toolbar in your VM window, as the following image shows:

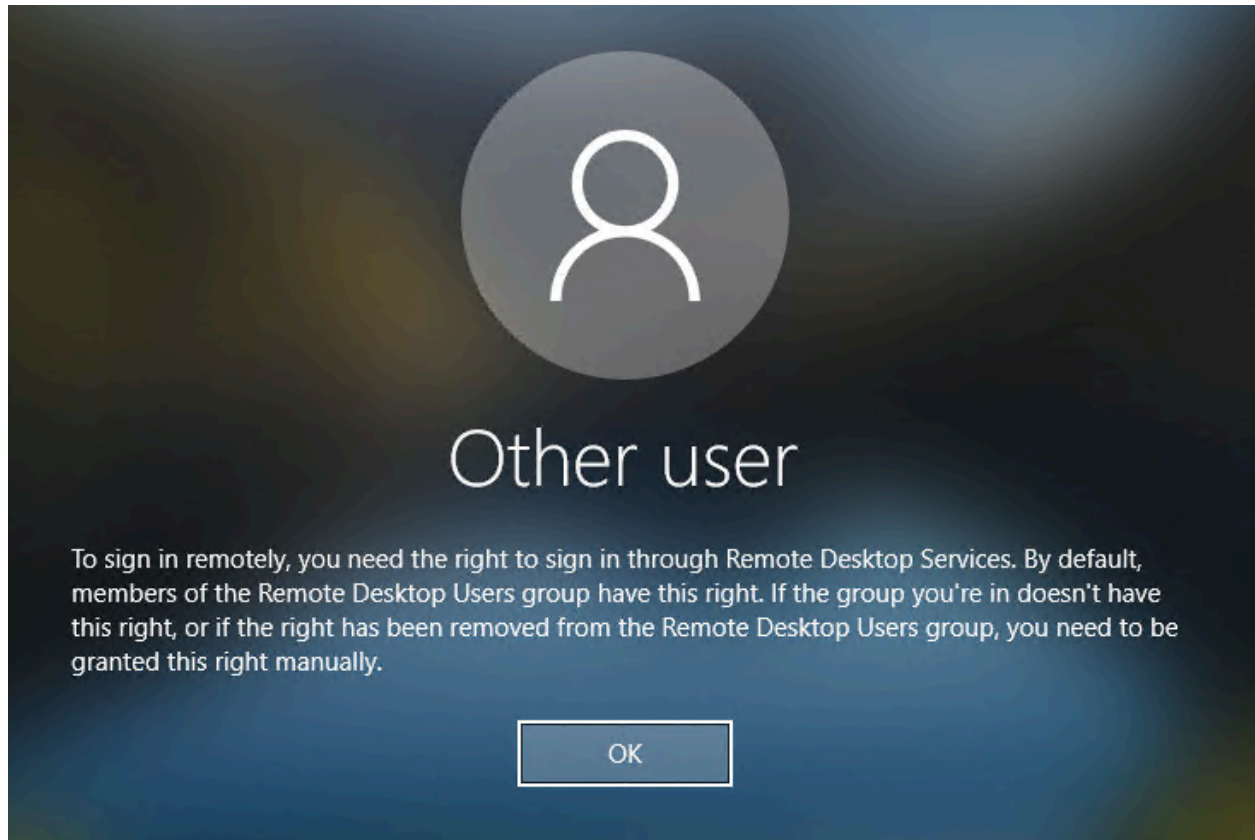

This will toggle it from **Enhanced Session Mode** to a **Basic Session** window.

- Pressing it again will return you to **Enhanced Session Mode**, where you can copy and paste into your VM.

Issue: Unable to Log In with Remote Desktop Users

When attempting to log in to the domain users on the Windows 10 machine, you may encounter the error shown in the following image, referring to remote desktop permissions: **To sign in remotely, you need the right to sign in through Remote**

Desktop Services. By default, members of the Remote Desktop Users group have this right. If the group you're in doesn't have this right, or if the right has been removed from the Remote Desktop Users group, you need to be granted this right manually.

The quickest way to fix this is to toggle the virtual machine's **Enhanced Session Mode** to **Basic**.

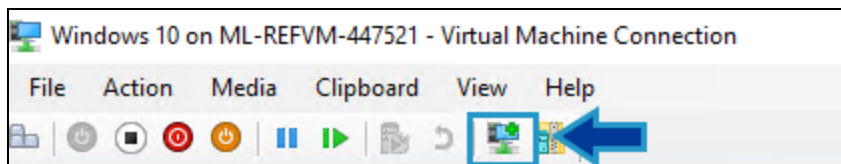

Toggling Hyper-V Enhanced Session Mode

The Windows Azure Hyper-V Lab should already be configured so that the virtual machines have **Enhanced Session Mode** enabled.

- **Enhanced Session Mode** allows you to copy and paste directly into the virtual machines. You won't, however, be able to log in to the virtual machines as a domain user with Enhanced Session Mode enabled.

Complete the following instructions to ensure that your Windows 10 machine has the latest group policies and to disable **Enhanced Session Mode**:

- Log in to the Windows 10 machine as `sysadmin` and run `gupdate` (in CMD or PowerShell) to pull your latest Active Directory changes.
- Click the enhanced-session-mode icon, as shown in the following image, to toggle the virtual machine into **Basic session** mode:

If you hover your mouse over the icon, a tooltip will display the mode you are toggling to.

- After toggling to **Basic session**, select **Other user** to log in to your domain user.
- Once you are done using your domain user, you can toggle **Enhanced Session Mode** back on, which will log you out of the virtual machine and return you to the login screen.
