

Solution Guide: Windows Port Scanning

In this activity, you reconducted scanning in order to determine if any Windows machines are on the network.

- You used Nmap to scan the network once again, this time looking for any Windows machines.
- This scan gave you an idea of what machines to target next.

Instructions

On your Kali machine, perform an Nmap scan of the network you're on, then answer a few questions.

1. Perform `ip addr` to identify your IP address, and perform an Nmap scan on that subnet (/24) to identify all machines on that network.
2. Based on what you learned, answer the following questions:
 1. How many Windows machines are on the network?
 - Two machines
 2. What ports or services are open on the machines that suggest that they're Windows machines?
 - 445 SMB, 139 RPC/SMB, 3389 RDP, 88 Kerberos
 3. Can you tell which machine is the domain controller?
 - The machine with port 88 open is always the DC due to how Kerberos operates.
