

Module 18 Day 2: SPL Search

Activity Instructions

1. As the SOC manager at OMP, you are asked to analyze the company's vulnerability-scanning logs to determine the vulnerabilities of OMP's technical assets.
2. To accomplish this, you must design SPL searches to run against the vulnerability-scanning log file `nessus.txt`.
3. These searches can be used to quickly look up existing vulnerabilities on your operating systems or devices.

Instructions

1. Using SPL, design searches to display the following data from the `nessus` logs:
 - Display results where OS contains "Windows".
 - Display results where OS contains "Linux".
 - Display results where `dest_ip` is `10.11.36.4`.
 - Display results where `dest_ip` starts with `10.12.34`.
 - Hint: Use wildcards in your searches.
2. Run your designed queries within Splunk and determine the count returned for each query.

Bonus

- Design an SPL search to display results where the signature contains an RDP man-in-the-middle weakness.
